1.Power Pivot components and tasks:

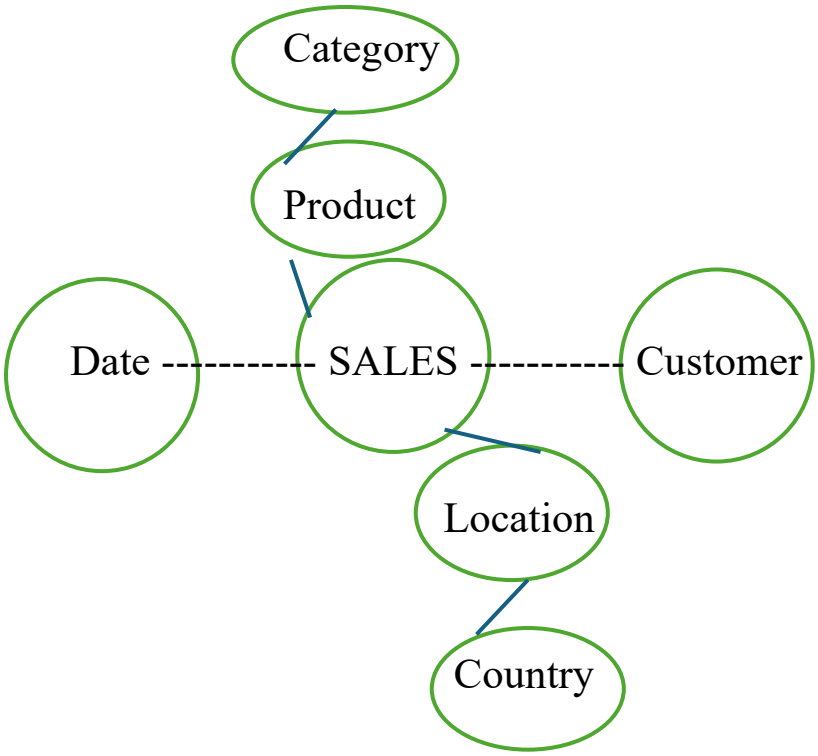

Power Pivot is an Excel tool used to manage and analyze large amounts of data. Its main components include the Data Model, which stores and organizes data; Relationships, which connect different tables; DAX, which is used to create calculated columns and measures; and Power Pivot Window, which helps manage tables and relationships.

2. Views in Power BI Desktop: Power BI Desktop mainly has three views: Report View, which is used to create charts, tables, and dashboards; Data View, which is used to view and examine the data and create calculated columns; and Model View, which is used to create and manage relationships between tables and understand the data model.

3. Star and Snowflake Schema: A Star Schema has one central fact table connected directly to several dimension tables, for example, Sales connected to Product, Customer, Date, and Store.

A Snowflake Schema is a more normalized version where dimension tables are further divided into related tables, for example, Product connected to Category.

4. Fact and Dimension Tables: A Fact Table contains measurable business data such as sales, quantity, and profit, while a Dimension Table contains descriptive information such as product name, customer details, date, and location. In simple terms, the fact table tells what happened, while dimension tables tell by whom, what, where, and when.
