1. What is DAX? Why is it used?

DAX (Data Analysis Expressions) is a formula language used in Power BI, Power Pivot, and Analysis Services. It is used to create calculated columns, measures, and calculated tables for data analysis.

2. What are the data types supported by DAX?

DAX mainly supports Whole Number, Decimal Number, Currency, Date/Time, True/False (Boolean), Text, and Blank data types.

3. What is the difference between a calculated column and a measure?

A calculated column calculates a value for each row and stores the result in the table. A measure calculates a value dynamically based on the current filter or report context and is mainly used in visualizations.

4. How to exclude all filters while calculating any measure?

Use the ALL() function inside CALCULATE(). For example: CALCULATE([Total Sales], ALL(Sales)). It removes the filters from the Sales table while calculating the measure.

5. What are circular dependencies? How can you avoid them?

A circular dependency occurs when two or more calculated columns or measures depend on each other directly or indirectly, creating a loop. To avoid them, do not create formulas that reference each other, use proper table relationships, and simplify DAX expressions by separating calculations into independent measures or columns.
