Multiple Ways to Create a New Dataflow in Power BI

A dataflow in Power BI is a collection of data transformation steps that can be reused by multiple reports and datasets. It helps extract, clean, and prepare data in the Power BI Service.

There are several ways to create a new dataflow:

1. From a Workspace

1. Open Power BI Service.
2. Go to the required Workspace.
3. Select New.
4. Choose Dataflow.
5. Select Define new tables.
6. Choose the required data source.
7. Connect to the source and transform the data using Power Query.
8. Save the dataflow.

2. From an Existing Dataflow

You can create a new dataflow by referencing or copying entities from an existing dataflow. This is useful when you want to reuse already prepared data and transformations.

3. Using Import/Export or Templates

Dataflows can also be created using exported dataflow definitions/templates. This allows organizations to reuse an existing dataflow structure in another workspace or environment.

4. Using Power Query Online

A dataflow can be created by opening the Power Query experience in Power BI Service, selecting the required data source, and creating transformation steps. After completing the transformations, the query can be saved as a dataflow.
